AI Algorithm: Evaluation of the Opponent’s Behavior

By FELLAH Arij

STEP 1: Collect the opponent’s move history

(movements, captures, sacrifices, etc.)

```
function: evaluate_behavior(move_history, board 9x9):

    Metrics = {
        capture = 0,
        isolated_pawn = 0,
        defensive_move = 0,
        aggressive_move = 0,
        total = 0
    }
```

STEP 2: Measure quantitative indicators

For each move in the opponent’s move history:

```
Metrics.total += 1

If it is a capture:
    Metrics.capture += 1

If it creates an isolated pawn:
    Metrics.isolated_pawn += 1

If it is a defensive move:
    Metrics.defensive_move += 1
```

```
If it is an aggressive move:
    Metrics.aggressive_move += 1
```

STEP 3: Compute a score for each category

(Aggressiveness, Defense, Imprudence)

```
Aggressiveness = Metrics.aggressive_move / Metrics.total
Defense        = Metrics.defensive_move / Metrics.total
Imprudence     = Metrics.isolated_pawn / Metrics.total
```

STEP 4: Result analysis

- If **Aggressiveness ≥ 0.5**:
  Strengthen and protect isolated pawns + set traps
- If **Defense ≥ 0.5**:
  Target the opponent’s isolated pawns + advance slowly and control more space + force favorable moves
- If **Imprudence ≥ 0.5**:
  Prioritize easy captures + avoid overly cautious defenses
- If **Imprudence = Defense + Aggressiveness**:
  Observe move by move + defend against attacks and attack against defensive play
